Parasitic fibroids often present a diagnostic challenge due to the unusual locations that they arise from. We present a mini case series of rare extra-uterine fibroids. In recent years, this has been associated with morcellated hysterectomies or myomectomies.

Our patients underwent open hysterectomy or myomectomy with positive histology diagnosis subsequently. Two had previous laparoscopic myomectomies while the other two has no significant past surgical history of note.

While careful and diligent removal of fibroid tissue is advised after morcellation, spontaneous occurrence is associated with congenital mullerian duct fusion defects. Long term follow up is required to look out for possible recurrence and treatment option should be available.
