In 2010 the National Institute for Health and Care Excellence has published a national guideline (GC 027) which has shaped suspected cancer referrals in the United Kingdom. Since the implementation of the 2 Week wait referral pathway for suspected cancer referrals the Breast Team at Norfolk & Norwich University Hospital has used the triple assessment method, which includes examination, imaging and biopsy to efficiently diagnose and treat patients. Data from 87 patients that were referred to the one stop clinic by local general practitioners was collected and analyzed to determine whether suspected cancer referrals have indeed a higher rate of histologically diagnosed carcinoma and whether the current NICE approved management guidelines have an optimal detection rate. Management of suspected breast cancer patients using these guidelines did allow a high sensitivity of malignancy detection, resulting in appropriate prioritizing of same day triple assessment management.
